Title: FILTER DEVICE

Inventors: Walter Best

Uwe Schumacher

Attorney Docket No.: 16202.640

For hot gas filtration, for example the filtration of diesel engine exhaust gases, increasing use is being made of filter elements made of porous ceramic material, particularly successful here is the SiC ceramic material that is described in EP 796 830 A1. It is chemically stable and has high thermal conductivity, temperature resistance, and thermal shock resistance. As is evident from WO 93/13303 and EP 1 013 328 A2, filter elements of this kind are combined into one filter element group or several of them, in which the filter elements lie side by side next to one another and are flowed through in parallel. Located between the filter elements are contact layers made of material expanded by the action of heat. The filter element groups are surrounded by housings that can also be replaceable.

Sub 27.02.07

US Patent 4,505,107 describes a filter device that contains, in a filter housing, a filter element made of porous ceramic foam. Provided on its end face is a heating device

3/27/07  
Su 27.08.07

The basic idea of the invention is thus to provide electrical cleaning but to limit it to some of the filter elements and accordingly to keep the outlay for equipment comparatively low. This is based on the consideration, already belonging to the invention, that the exhaust gas volume is low in precisely those operating states in which  
5 combustion of the carbon by way of the exhaust gas is not successful, and accordingly even a partial cleaning is sufficient to ensure a sufficiently low exhaust gas pressure. Complete regeneration occurs when the diesel engine has warmed up and greater load states are demanded. The two cleaning methods thus complement one another with little additional outlay for equipment. For the other filter elements, furthermore, their electrical  
10 conductivity does not need to be taken into account.

In an embodiment of the invention, provision is made for the first filter element(s) to be arranged at the center, since energy conversion there is particularly effective. The possibility also exists, however, for the first filter elements to be arranged in distributed fashion in the filter element group, greater flexibility being thereby achievable. In this  
15 case the possibility exists of cleaning the filter elements alternately by way of a corresponding circuit.

The invention does not exclude the fact that the second filter elements are also made of electrically conductive ceramic material. This is a good choice in particular if the second filter elements resting against the first filter element(s) are in electrically  
20 conductive contact with the first filter element(s). Concurrent heating of the second filter elements can thereby be brought about. By appropriately designing the electrical conductivity of the first and second filter elements and the transition between the two, the concurrent heating can be adapted in customized fashion to respective conditions. The possibility also exists, however, of producing the second filter elements from an

electrically nonconductive material, if active concurrent heating is not desired. In that case concurrent heating is brought about by thermal conduction.

According to a further feature of the invention, provision is made for the thermal conductivity of the second filter elements to be greater than or less than that of the first  
5 filter element or elements. The concurrent heating of the second filter elements can thereby be adjusted accordingly.

The filter elements can be arranged in direct contact with one another. For an assemblage, it is advisable to arrange contact layers between the filter elements. The electrical and thermal resistance can be influenced to the particular degree desired by way  
10 of the material and thickness of the contact layers. Contact layers that are made of the same ceramic base material as the filter elements are particularly suitable for this purpose.

If concurrent heating is desired, the contact layers can be designed to be electrically conductive. Contact layers like those described in EP 0 943 593 A1 have proven successful. The electrical conductivity of the contact layers should be lower than  
15 that of the first filter elements.

The contact layers can be configured in such a way that they directly connect the filter elements. Separate contact layers with no material connection to the filter elements can, however, also be provided. In that case the filter elements are held together by a housing that surrounds them.

20 The thermal conductivity of the contact layers can be of the same order of magnitude as that of the first or second filter elements.

According to a further feature of the invention, provision is made for the filter elements to comprise, next to and alternating with one another, inflow conduits and outflow conduits that are separated by porous, filtrationally effective longitudinal walls,

the inflow conduits being open on the inflow side and closed on the outflow side, and the outflow conduits being closed on the inflow side and open on the outflow side. Inflow and outflow conduits having a rectangular, in particular square, cross section have proven successful. In this context, the outer walls of the filter elements should be of particle-tight, in particular gas-tight, configuration. The filter elements can have a rectangular, square, oval, round, and/or shell-shaped cross section.

The filter element group(s) is/are advantageously surrounded by a housing having a gas inlet and gas outlet; each filter element group can be surrounded by a separate housing if multiple filter element groups are present. A corresponding embodiment is evident, for example, from EP 1 013 328 A2.

The invention is illustrated in more detail, with reference to exemplary embodiments, in the drawings, in which:

- FIG. 1 shows a first filter element group in an end view;
- FIG. 2 shows a second filter element group in an end view;
- FIG. 3 shows a third filter element group in an end view;
- FIG. 4 shows a fourth filter element group, having an electrical terminal piece, in an end view; and
- FIG. 5 shows a longitudinal section through a filter housing having a fifth filter element group.

Filter element group 1 depicted in FIG. 1 comprises a first filter element 2, round in cross section and made of an electrically conductive ceramic material, that is surrounded by four shell-shaped second filter elements 3, 4, 5, 6 made of ceramic material. Flow through all the filter elements 2, 3, 4, 5, 6 is axial, i.e. perpendicular to the plane of the drawing. In known fashion they have for that purpose, adjacently and alternatingly, inflow and outflow conduits that are separated by porous filtrationally effective longitudinal walls, the inflow channels being open on the inflow side (here, at the end face) and closed on the outflow side, and the outflow conduits being closed on the inflow side and open on the outflow side. The inflow and outflow conduits are arranged in checkerboard fashion.

The central first filter element 2 is equipped (although this is not depicted here in detail) at both end faces with electrical terminals like those described in EP 0 943 593 A1. First filter element 2 can be connected to an electrical circuit and thus acted upon by current. The electrical resistance of first filter element 2 is such that when acted upon by current it heats up in such a way that <sup>soot</sup>~~carbon~~ which has deposited there combusts.

Second filter elements 3, 4, 5, 6 are in contact against first filter element 2 by way of a contact layer (not depicted here in detail). They have no electrical terminals.

Depending on the type of contact layers and the thermal conductivity of second filter elements 3, 4, 5, 6, the latter are concurrently heated when first filter element 2 is acted upon by current; the heating can even proceed to the point that at least partial burn-off of <sup>soot</sup>~~the carbon~~ occurs in these filter elements 3, 4, 5, 6 as well. If this is to be encouraged, second filter elements 3, 4, 5, 6 can also be made from an electrically conductive ceramic material.

Filter element group 1 is intended to be incorporated into the filter housing of a filter device, the filter device then being installed in the exhaust system of a diesel engine.

~~Carbon~~ <sup>Soot</sup> cleaning is usually performed by way of corresponding exhaust gas processing.

for example elevating the exhaust gas temperature to a level at which the ~~carbon~~ <sup>soot</sup> combusts.

5 combusts. If the vehicle in question is used only at low load or in short-distance driving,

the risk exists that operating states in which the exhaust gas temperature is sufficient for

combustion of the carbon will not be attained. In that case electrical current is delivered

to first filter element 2 so that it heats up to a temperature at which the ~~carbon~~ <sup>soot</sup> combusts.

The exemplary embodiment of FIG. 2 shows a filter element group 11 in which a

10 first filter element 12 is arranged centrally and is surrounded by eight second filter

elements 13 through 20. In contrast to the embodiment of FIG. 1, here filter elements 12

through 20 have a square cross section, so that filter element 11 also has a square cross

section. Except for the differences in cross section, the description of the exemplary

embodiment shown in FIG. 1 is applicable.

15 FIG. 3 depicts a further exemplary embodiment of a filter element group 21 in

which two first filter elements 22, 23 are arranged at a distance from one another and

separated by a second filter element 24. First filter elements 22, 23 are surrounded by

further second filter elements (labeled <sup>25</sup> ~~24~~ by way of example), thus yielding an overall

square cross section for filter element group 21. Filter elements 22, 23, 24, 25 themselves

20 have a square cross section.

With regard further to first and second filter elements 22, 23, 24, 25, the reader is referred to the description of filter elements 2 through 6 shown in FIG. 1. In the case of filter element group 21, the possibility exists of performing cleaning of first filter

elements 22, 23 independently of one another and at different times, by providing a corresponding circuit.

Filter element group 31 depicted in FIG. 4 has an overall circular cross section and is similar to filter element group 1 shown in FIG. 1, with the difference that the first, center filter element 32 has a square cross section. It is surrounded by four shell-shaped second filter elements 33, 34, 35, 36. Filter element group 31 is surrounded by a circular housing 37, an insulation layer 38 being present between filter element group 31 and housing 37. The individual filter elements 32, 33, 34, 35, and 36 are separated from one another by contact layers (labeled 39 by way of example). Contact layers 39 have a lower electrical conductivity than filter elements 32, 33, 34, 35, 36.

Placed onto the end face of first filter element 32 is a terminal piece 40 that has the same cross section as first filter element 32 and, as depicted, comprises square inflow conduits. Terminal piece 40 is depicted again below filter element 31, rotated 90 degrees. Terminal piece 40 is connected via contact layer elements (labeled 41 by way of example) to the end face of first filter element 32. On the outer side, terminal piece 40 has a connector flange 42 that is equipped with a connector screw 43 for attachment of an electrical cable. It is understood that a corresponding terminal piece is present on the other end face of first filter element 32.

Filter element group 51 depicted in FIG. 5 is housed in a housing 52 that first expands conically in the flow direction and then contracts conically again. Only a single filter element 53, which extends over the entire width of housing 52, is shown in section. The other filter elements are not visible.

The sectioned depiction shows clearly that inflow conduits (labeled 54 by way of example) and outflow conduits (labeled 55 by way of example) alternate in the section
